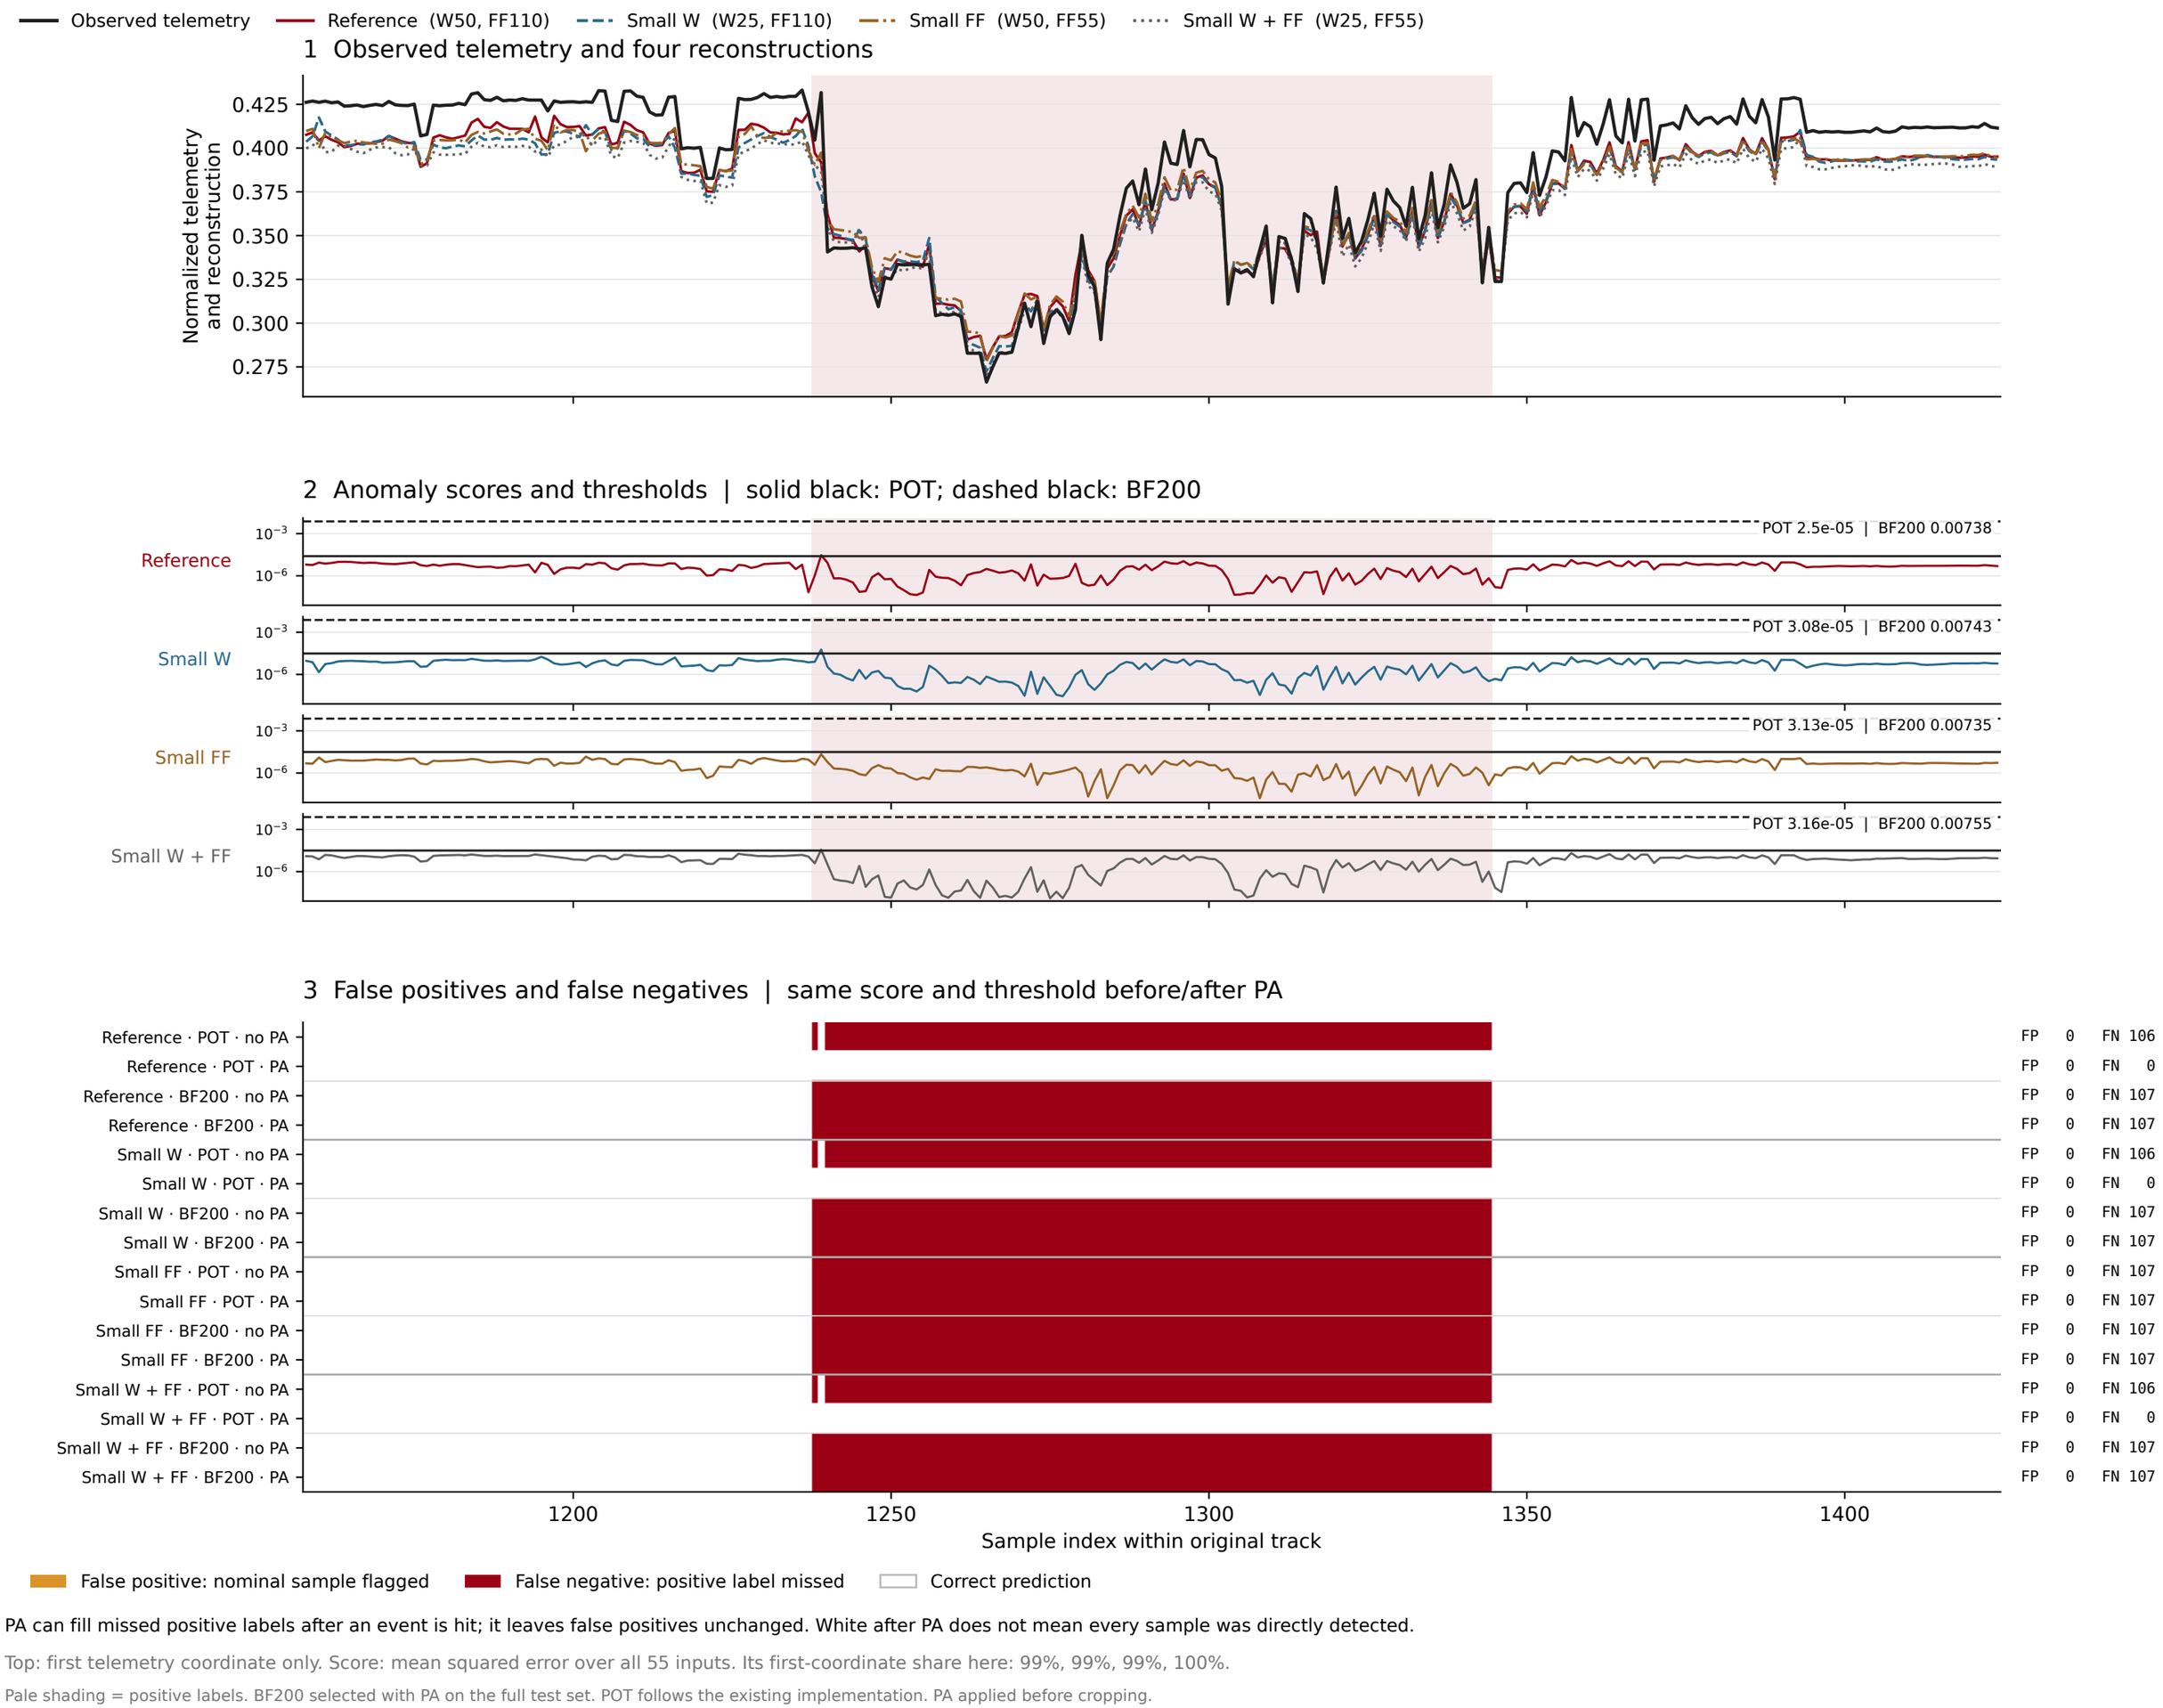
MSL | P-11 | Labelled anomalous interval

TranAD+ architecture throughout | seed 2026 | 50 epochs | fixed alpha = 0.5



PA can fill missed positive labels after an event is hit; it leaves false positives unchanged. White after PA does not mean every sample was directly detected.

Top: first telemetry coordinate only. Score: mean squared error over all 55 inputs. Its first-coordinate share here: 99%, 99%, 99%, 100%.

Pale shading = positive labels. BF200 selected with PA on the full test set. POT follows the existing implementation. PA applied before cropping.
